

# EcoStruxure Value Advisor — Demo Briefing

Sep 27, 2026 · @Rose

This is the reference page for the pitch: where every number on screen comes from, why the tool is a real commercial argument for Schneider Electric, what to volunteer about its limits before you're asked, and exactly what to click during the demo.

## Where each figure comes from

Every number the calculator produces traces to a version-stamped source file, not a guess — this is the table to point to if a judge asks "where did this come from."

| Figure                                                       | Value used                                                   | Source                                                               | Notes                                                                                                                                                              |
|--------------------------------------------------------------|--------------------------------------------------------------|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Grid Emission Factor                                         | 0.402 kg CO2/kWh                                             | EMA Singapore, Grid Emission Factor 2024                             | Singapore-specific, not an international proxy                                                                                                                     |
| Electricity tariff                                           | S\$0.3191/kWh                                                | SP Group, Q3 2026 published tariff                                   | Refreshed quarterly; 2%/yr escalation assumed on top for projections                                                                                               |
| Carbon tax schedule                                          | S\$25 (2024-25) to S\$45 (2026-27), indicative S\$65 by 2030 | NEA / MSE, under the Carbon Pricing (Amendment) Act 2022             | The first two steps are legislated law, not a forecast                                                                                                             |
| Sector energy-intensity bands (best/average/poor, kWh/m2/yr) | e.g. Office/Professional Services: 111/144/182               | BCA Building Energy Benchmarking Report (primary-source spreadsheet) | Corrected this build cycle after an earlier search pass returned conflicting figures — verified against BCA's own dataset directly rather than secondary summaries |

| Figure                           | Value used                                                                                                                           | Source                                                    | Notes                                                                                                                                             |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ECM saving ranges and cost tiers | e.g. LED retrofit 30-60% saving                                                                                                      | ASHRAE, US DOE, ENERGY STAR                               | Cross-checked against Schneider's own published case studies; an "unusually high" warning fires if a computed result falls outside real precedent |
| Scope 3 methodology              | Spend/activity-based EEIO                                                                                                            | US EPA EEIO v2.0; UK DESNZ/DEFRA conversion factors       | Quantified for reporting, deliberately not monetised — Schneider doesn't control a client's supply chain, so no product claim is attached to it   |
| Energy Efficiency Grant          | Up to S\$30,000, 70% co-funded                                                                                                       | EnterpriseSG / GoBusiness                                 | Shown as a separate nudge, never folded into the modelled savings                                                                                 |
| Case-study proof points          | JLL APAC HQ (30% cut), Samwoh Smart Hub (S\$220k/yr, ~4yr payback), Marriott (10-15%), Kallang Pulse Schneider SG HQ (3.3yr payback) | Schneider Electric's own published, verified case studies | Used as "this is achievable" evidence, never as the basis for any specific company's own modelled number                                          |

## Why this works for Schneider Electric

It replaces "we think you could save 15-30% of your energy bill, roughly" with a number a CFO can actually approve — that gap is the entire commercial argument.

- **Closes the credibility gap that kills capex.** A capex committee compares proposals on cost, payback, and certainty. A blended industry-average percentage loses to a modelled return with named measures, even when the underlying opportunity is bigger.
- **Demonstrated on the judges' own buildings, not a synthetic example.** The personalised Thales, Monee, and Garena reports use only public information run through the live engine — makes the pitch visceral rather than hypothetical.
- **Ranks by real payback, not visibility.** Facilities teams default to whatever's visible (lighting). In Singapore's cooling-dominant climate, HVAC and chiller-plant measures are usually the biggest lever — the tool routes attention and budget there first.
- **Positions Schneider as the rigorous, transparent advisor,** not a vendor pushing a black-box percentage — a real differentiator against anyone quoting an unsourced range.
- **Reusable, not a one-off demo.** Same engine, same architecture extends to any sector or market by swapping the underlying data files — this is a sales and engineering tool, not a single pitch prop.

## Limitations to lead with

Volunteer these before a judge asks — disclosing them first is itself part of the credibility pitch.

- **Confidence is rated Low ( $\pm 27.5\text{-}35\%$ )** whenever electricity use is estimated from floor area rather than a real meter reading — shown on every screen and report, never hidden. It sharpens automatically once real kWh data is entered.
- **Cost figures are generic order-of-magnitude tiers** (e.g. S\$5,000-20,000 for a "low" cost measure), not a site-specific quote.
- **Landlord-controlled measures need explicit exclusion for tenants.** Demonstrated live with Monee and Garena: a naive full-catalog sum gave an incredible 37% on an already Green-Mark-Platinum building neither company controls the chiller plant of — excluding what a tenant can't act on brought it to a defensible 28%, using the same engine with nothing hand-edited.
- **Scope 1 defaults to 0 without input.** A data gap where no public information exists, not a claim that real direct emissions are zero.
- **This is a calculator demonstration, not a professional energy audit.** Positioned deliberately as the first number in the room, not the last word — a Schneider advisor working from real utility bills produces a materially more precise version of every figure shown.

## Demo script

1. **Open the live calculator, not a screenshot.** Sets the tone immediately: this is a working tool, not a mockup.
2. **Walk the wizard briefly** — business info, then energy & fuel. Say out loud: "completable from a utility bill alone — no consultant, no site visit, to get a first number."
3. **Land on the Results headline card.** Saving range, payback, confidence rating, in one glance — this answers "is this worth my time" before anything else.
4. **Click through the Top 3 recommended measures.** Open one for its evidence and how-to-implement text. This is the credibility moment — a named, sourced measure, not a guess.
5. **Scroll to "How we got to X%"** and walk the four-step chain live for one measure. This is the standout differentiator versus a single blended percentage — slow down here.
6. **Tick and untick a measure in the "Cost of doing nothing vs. acting" chart.** Shows the tool responding live, not a static slide — a genuine "alive" moment.
7. **If demoing on Monee's or Garena's own profile: point out the landlord-controlled tag** on the chiller measures. Ties directly to their own building and shows the tool catching an implausible number and correcting it honestly, live.
8. **Show the Limitations section / confidence rating before anyone asks "how sure are you."** Disarms the skepticism question pre-emptively — pairs directly with the Limitations section above.
9. **Close on the PDF export.** "You can walk away with your own version of this today" — and note the three personalised reports (Thales, Monee, Garena) already exist as leave-behinds if the room wants to see their own company's numbers without live data entry.
